AB An antigenic prepn. is provided contg. an outer membrane protein assocd. with **pathogenic** strains of **Leptospira**. The protein has been designated "LipL46" for "lipoprotein from Leptospira" and because the isolated polypeptide migrates to a position corresponding to a mol. wt. of 46 kDa in a denaturing polyacrylamide gel. The invention provides polynucleotides encoding LipL46 and antibodies that bind the protein which are useful in the diagnosis of leptospirosis. In addn., LipL46 can be used immunol. as a vaccine for spirochete-assocd. pathologies.

AB To investigate the contribution of the previously demonstrated in vitro apoptosis to the **pathogenesis** of **leptospirosis**, guinea **pigs** were infected with

Leptospira interrogans serovar icterohaemorrhagiae strain Verdun and sequentially killed to collect target organs involved in the natural history of the disease (liver, kidneys, lungs, spleen and heart). The combination of histopathol. procedures and a specific TUNEL assay showed a significant Leptospira-induced programmed cell death of hepatocytes with a peak at 48 h post inoculation. Hepatocyte nuclei showed morphol. changes including fragmented and condensed nuclei. This phenomenon occurred early in the course of the disease at a time where infecting leptospires were present at a low d. between the liver parenchyma cells.

AB Novel isolates of the spirochaete Leptospira and antigens derived from them that can be used in the diagnosis and prophylaxis of disease are described. More particularly, the present invention is directed to a new serovar of Leptospira designated as serovar **hurstbridge** or serogroup **Hurstbridge** or L. fainei. The bacteria were isolated from **pigs** at slaughterhouses in Australia. The new isolate is a member of the **pathogenic** grouping of **Leptospira** but is distinct from known

serovars. It is most similar to the lyme serovar of L. inadai.

AB **Pathogenic leptospires** can be causative agents of reproductive problems in **pigs**. Cultures of uteri and kidneys from two **pig** herds in New South Wales and Victoria (Australia) yielded five strains identified as Leptospira on morphol. and cultural grounds. Phenotypic characteristics (growth at 13 and 30.degree.C, growth in the presence of 8-azaguanine) were intermediate between those of **pathogenic** and saprophytic **leptospires**. No cross-agglutination was obsd. with ref. antisera representing the 24 pathogenic serogroups and the main saprophytic ones. Antiserum against one of the strains did not agglutinate ref. strains representative of any serogroup. This provided evidence of a new serovar, designated **hurstbridge**. Genomic characterization of the five strains was achieved using five mol. approaches. Mapped restriction site polymorphisms in the rrs (16S rRNA) gene were not related to those of any ref. strains. Arbitrarily primed PCR fingerprints suggested clonality of the five strains. The strains all showed an identical and unique PFGE profile. PCR, using primers specific for the rrs gene of **pathogenic leptospires**, amplified corresponding sequences from the strains. DNA-DNA hybridization (and reciprocal expts.) using the S1 nuclease/TCA method was performed between one of the strains and the ref. strains of Leptospira species. The homol. ranged from 0 to 36% (the latter being with Leptospira inadai) thus satisfying the criterion of a new species, Leptospira fainei (type strain BUT 6T). Phylogenetic anal. of 16S rRNA sequences showed that L. fainei and L. inadai formed a clade sep. from the previously recognized "saprophyte" and "pathogen" clades.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB Interactions of virulent Leptospira interrogans serovar icterohaemorrhagiae strain Verdun with Vero cells (African green monkey kidney fibroblasts) and a monocyte-macrophage-like cell line (J774A.1) were assayed by a double-fluorescence immunolabelling method. Infectivity profiles were investigated according to (i) the duration of contact between leptospires and eukaryotic cells and (ii) the no. of in vitro passages after primary isolation from lethally infected guinea **pigs**. Comparative expts. were conducted with the corresponding high-passage avirulent variant and the saprophytic leptospire Leptospira biflexa Patoc I. In Vero cells, virulent leptospires were quickly internalized from 20 min postinfection, whereas avirulent and saprophytic strains remained extracellularly located. In addn., the virulent strain demonstrated an ability to actively invade the monocyte-macrophage-like J774A.1 cells during the early stages of contact and to induce programmed cell death, as shown by the detection of oligonucleosomes in a quant. sandwich enzyme immunoassay. In both cellular systems, subsequent in vitro subcultures demonstrated a progressive decrease of the invasiveness, pointing out the necessity of using primo cultures of Leptospira for virulence studies. Invasiveness of virulent leptospires was significantly inhibited with monodansylcadaverine, indicating that internalization was dependent on receptor-mediated endocytosis. Invasion of epithelial cells and induction of apoptosis in macrophages may be related to the **pathogenicity** of **Leptospira**, and both could contribute to its ability to survive in the host and to escape from the immune response.

DOCUMENT TYPE: Journal
LANGUAGE: English

AB Comparative anal. of the enzymic profiles of 58 spirochaetal isolates clearly differentiated borrelias from leptospires, serpulinas and a treponeme. Strains of both Borrelia burgdorferi and Borrelia hermsii characteristically produced significant amts. of leucine arylamidase. This enzyme activity was not unique to borrelias but was also detected among **pathogenic** and non-**pathogenic leptospira** serovars. This fact, however, did not hamper a correct differentiation of borrelias from these spirochaetes, because leptospires possessed unique enzyme profiles. The API ZYM system could not differentiate the human strains of B. burgdorferi from those isolated from ticks, or from B. hermsii. Treponema phagedenis could be differentiated from all the other spirochaetes by the prodn. of .alpha.-fucosidase. These results indicate that human and animal intestinal spirochaetes have many common enzyme activities. All strains produced reactions of max. intensity when tested for the presence of .beta.-galactosidase activity. However, the avian strains lacked esterase (C4) which was present in human and **swine** intestinal spirochaetes. All strains of Serpulina hyodysenteriae, and Serpulina innocens as well as the human intestinal spirochaete strain HRM-14 showed .alpha.- and .beta.-glucosidase activity. Both enzyme activities were absent or insignificant in most other intestinal spirochaetes examd.: 25 different human strains, non-pathogenic **swine** strain M1 and the avian strain 4742. However, **swine** strain LL3 and avian strain 1380 showed some .beta.-glucosidase activity.

AB We have developed an assay for the detection of **pathogenic Leptospira** that is based on the polymerase chain reaction. With the combination of agarose gel electrophoresis and blotting,

pathogenic Leptospira can be discriminated specifically from nonpathogenic **Leptospira** and other bacterial species. This method, based on the amplification of 16S rRNA sequences, is able to detect 10 leptospiral cells/mL in cattle urine samples and 100 leptospiral cells/mL in **pig** urine samples. Using this assay leptospires were detected in urine samples from cattle that were exptl. infected with Leptospira interrogans serovar hardjo type hardjobovis.

DOCUMENT TYPE: Journal
LANGUAGE: English

AB The outer membrane proteins of seven ref. strains of **pathogenic Leptospira** (L. alstoni serovar grippotyphosa, L. borgpetersenii serovar hardjo, and L. interrogans serovars autumnalis, Bratislava, canicola, icterohemorrhagiae, and pomona) were investigated to identify common surface-exposed outer membrane proteins. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis of sodium-N-lauroylsarcosinate-insol. outer membrane-enriched fractions of the ref. serovars and two field isolates of serovars hardjo and pomona revealed six common protein bands with approx. mol. masses of 77, 66, 42, 35.5, 24, and 18 kDa. At times the 35.5 kDa endoflagellar band resolved into two distinct bands, 35.5 kDa and 34 kDa. Immunoblotting of the same fractions using rabbit leptospiral antibodies showed six bands to be common (66, 59.5, 44, 42, 35.5, and 18 kDa). The 44 kDa band stained poorly with Coomassie blue but prominently by immunoblotting. Four ref. strains (serovars Bratislava, canicola, icterohemorrhagiae, pomona), and two field isolates of serovar pomona and one of serovar Bratislava were grown in low iron media to which the iron chelators 2,2'-dipyridyl or ethylenediaminehydroxyphenylacetic acid were added. No iron-dependent expression of outer membrane proteins was obsd. The only difference obsd. between the outer membrane proteins when ref. serovars of canicola or pomona were grown in dialysis bags in the peritoneum of **swine** or in vitro was the loss of the 77 kDa band from in vivo grown organisms. Treatment of whole leptospires with proteinase K did not remove the 77, 66, 59.5, or 42 kDa protein; these proteins may not be surface expressed or are inaccessible to the proteinase K. The 44 kDa band could not be evaluated by this method and the 18 kDa band was proteinase K

resistant.

CORPORATE SOURCE: Dep. Appl. Immunol., Natl. Inst. Health, Tokyo, 141, Japan
SOURCE: Can. J. Microbiol. (1989), 35(11), 1009-14
CODEN: CJMIAZ; ISSN: 0008-4166
DOCUMENT TYPE: Journal
LANGUAGE: English
AB Sonically disrupted cells from avirulent strain Shibaura of L. interrogans serovar copenhageni induced a skin reaction characterization by infiltration of polymorphonuclear leukocytes (PMN) assocd. with some edema in guinea **pigs**. To det. the substance inducing infiltration of PMN, lipids of avirulent strain Shibaura were extd. with chloroform-methanol-water after washing with acetone. The lipids comprised 28% of the dry wt. of the cell. When the lipids were further sepd. into water-methanol and chloroform fractions, the most severe PMN infiltration of all samples was seen in the skin inoculated with ext. recovered from the chloroform fraction. Neutral and polar lipids were detected after TLC of the chloroform ext. Neutral lipids were detected as free fatty acids (FFA). Fatty acids contained in polar lipids were mainly palmitic acid and palmitoleic acid, whereas FFA comprised 66.5% oleic acid. Skin reactions consisting of marked edema with mild infiltration of PMN were elicited by FFA. There was no obvious difference between a com. available FFA mixt. and the FFA from avirulent strain Shibaura. These observations suggest that FFA may play some role in the **pathogenesis** of **leptospirosis**.

TITLE: Active immunization of gilts against gonadotropin-releasing hormone: effects on secretion of gonadotropins, reproductive function, and responses to agonists of gonadotropin-releasing hormone
AUTHOR(S): Esbenshade, K. L.; Britt, J. H.
CORPORATE SOURCE: Dep. Anim. Sci., North Carolina State Univ., Raleigh, NC, 27695-7621, USA
SOURCE: Biol. Reprod. (1985), 33(3), 569-77

CODEN: BIREBV; ISSN: 0006-3363
DOCUMENT TYPE: Journal
LANGUAGE: English
AB Sexually mature gilts were actively immunized against gonadotropin-releasing hormone (GnRH) [9034-40-6] by conjugating GnRH to bovine serum albumin, emulsifying the conjugate in Freud's adjuvant, and giving the emulsion as a primary immunization at Week 0 and as booster immunizations at Weeks 10 and 14. Antibody titers were evident by 2 wk after primary immunization and increased markedly in response to booster immunizations. Active immunization against GnRH caused gonadotropins to decline to nondetectable levels, gonadal steroids to decline to basal levels, and the gilts to become acyclic. Prolactin [9002-62-4] concns. in peripheral circulation were unaffected by immunization against GnRH. The endocrine status of the hypothalamic-pituitary-ovarian axis was examd. by giving GnRH and 2 agonists to GnRH and by ovariectomy. An i.v. injection of 100 .mu.g GnRH caused release of LH [9002-67-9] and FSH [9002-68-0] in control animals, but not in gilts immunized against GnRH. In contrast, administration of 5 .mu.g D-[Ala6,des-Gly-NH210]-LH-RH ethylamide [52435-06-0] or 5 .mu.g D-[Ser-t-**But6**,des-Gly-NH210]-LH-RH ethylamide [57982-77-1] resulted in immediate release of LH and FSH in both control and GnRH-immunized gilts. Circulating concns. of LH and FSH increased after ovariectomy in the controls, but remained at nondetectable levels in gilts immunized against GnRH. Prolactin concns. did not change in response to ovariectomy. Apparently, cyclic gilts can be actively immunized against GnRH and this causes cessation of estrous cycles and inhibits secretion of LH, FSH, and gonadal steroids. Also, the functional integrity of the pituitary remained intact in animals actively immunized against GnRH, since gilts immunized against GnRH released both LH and FSH in response to 2 agonists of GnRH and prolactin secretion was unaffected by the immunization.

CODEN: JOIMA3; ISSN: 0022-1767
DOCUMENT TYPE: Journal
LANGUAGE: English
AB Thirteen hybrid cell lines which produce mouse monoclonal antibodies

to T. pallidum, the causative agent of syphilis, were established. All of the monoclonal antibodies react with T. palidum, Nichols strain, in ELISA and in immunofluorescence assays, but do not react with normal rabbit testicular tissue in the ELISA. Two of these antibodies reacted with the nonpathogenic treponemes T. phagedenis, biotype Reiter, T. refringens (Noguchi strain), T. vincentii, and T. denticola (strains 11 and W), as well as with Borrelia recurrentis, **Leptospira** interrogans, serogroup Canicola, and the **swine pathogen** T. hyodysenteriae. The remaining 11 antibodies react with 4 recently isolated strains of T. pallidum, but with none of the related nonpathogens nor with Borrelia or Leptospira. Thus, these monoclonal antibodies may identify antigenic determinants that are specific either for T. pallidum alone or for those treponemes which are pathogenic for humans. The mol. specificities of 6 of the 13 antibodies were detd. by Western blotting.

DOCUMENT TYPE: Journal
LANGUAGE: English
AB **Leptospira** Species are difficult to isolate from sperm specimens because rapid growth of the contaminant flora will kill the **pathogen**. The resistance of 5 Leptospira strains to different antibiotics was examd. with a view to an inhibition of such contaminant growth. Neomycin [1404-04-2], vancomycin [1404-90-6], nalidixic acid [389-08-2], streptomycin [57-92-1], chloramphenicol [56-75-7] all had an adverse influence on the multiplication phase, with vancomycin and nalidixic acid having the least effect. Streptomycin and chloramphenicol were most inhibitory. Thus, a combination of vancomycin and nalidixic acid was used for the recovery of leptospires from **porcine** sperm. To inhibit growth of Pseudomonas aeruginosa, polymyxin B was added. The strongly inhibitory action of polymyxin B on leptospiral growth could be eliminated by subculturing in a medium free from inhibitory substances after 2 days.

AB Different mechanisms responsible for the appearance of jaundice in leptospirosis caused by Leptospira icterohaemorrhagiae in guinea **pigs** were discussed. Hepatocellular damage was demonstrated with the presence to a lesser extent of intrahepatic biliary obstruction. A massive destruction of extravascular red blood cells liberated by the hemorrhagic diathesis, appeared to be the main cause in the genesis of jaundice. The latter was inhibited following the neutralization of the reticuloendothelial system of guinea pgs by .gamma.-irradn. before the infection.

AB In exptl. infections of guinea **pigs** with a virulent strain of Leptospira icterohaemorrhagiae widespread hemorrhages were obsd. Thrombocytopenia, prolongation of prothrombin, thrombin, partial thromboplastin and coagultion times, decrease of plasma fibrinogen, factor V, factor VIII, and the presence of fibrinogen degrdn. products were demonstrated. Treatment of infected guinea **pigs** with heparin prolonged life for 2-3 days. The histol. observations revealed that the main lesion was a severe injury of the vasculature, mainly arteries, arterioles, and capillaries. Most of the endothelial cells were affected or destroyed and the muscular fibers of arteries and arterioles were injured. With Martius-Scarlet-Blue, Weigert, or Picro-Mallory stains it was demonstrated that the organization seen in the vessels was not all

made of fibrin. Thus the hemorrhages obsd. in exptl. leptospirosis in guinea **pigs** are probably due to disseminated intravascular coagulation.

AB Male guinea **pigs** (av. wt. 250 g) were inoculated i.p. with a high dose of **pathogen** (**leptospiro** "Monica"). The effects of nonsteroid antiinflammatory drugs, including naphthipramide , were compared with untreated and steroid treated animals. Temp. curves, mortality rate, and mean survival time showed no statistical significance for any treatment over that of controls. These drugs also showed no infection enhancing effect as was previously re ported for cortisone.

AB WO 9942478 A UPAB: 19991110
NOVELTY - A substantially purified LipL32 Leptospira sp outer membrane polypeptide (I) is new . having a fully defined 272 amino acid sequence given in the specification.

DETAILED DESCRIPTION - (I) has a 272 amino acid (aa) sequence (given in the specification).

INDEPENDENT CLAIMS are also included for the following:

(1) an isolated polynucleotide (II) encoding (I);

(2) an isolated polynucleotide (III) selected from a 819 bp sequence (given in the specification), optionally where T is U, its complements and fragments of at least 15 bases that hybridize to (II);

(3) an expression vector comprising (II);

(4) preparation of (I);

(5) an antibody that binds (I);

(6) identifying a compound that binds (I) comprising incubating compound with (I) and measuring binding;

(7) detecting pathogenic spirochete comprising contacting sample with a reagent that binds a spirochete-specific cell component, and detecting binding;

(8) a kit for detection of (I) comprising carrier means containing at least one container with one containing a (I) binding agent;

(9) a kit for detection of (II) comprising at least one container comprising one with a polynucleotide that hybridizes to (II); and

(10) a kit for detection of antibody to (I) comprising a carrier means containing at least one container comprising one with (I).

ACTIVITY - Antipathogenic.

MECHANISM OF ACTION - None given.

USE - (I) and the antibody are useful as vaccines for inducing an immune response to a **pathogenic** spirochete, preferably Treponema, Borrelia or **Leptospira** (claimed). (II) is useful for detecting **pathogenic** spirochete in human, **swine**, **porcine**, feline, canine, equine, murine, cervine, caprine, lupine, leporidine and bovine, preferably Treponema, Borrelia or Leptospira (claimed). (I) is useful for detecting antibodies (claimed).

ADVANTAGE - Current vaccines have short-term immunity, as they include disrupted Leptospira sp outer membranes, unlike the new polypeptides.

TITLE: Seroprevalence of Leptospiral antibodies in commercial pigs in the Mashonaland East

Province of Zimbabwe

AUTHOR: Mavenyengwa, M.; Keller, E.; Munyombwe, T.
CORPORATE SOURCE: Central Veterinary Diagnostics and Research Laboratory, P.O. Box CY551, Causeway, Harare, Zimbabwe.

SOURCE: Zimbabwe Veterinary Journal, (1999) Vol. 30, No. 3/4, pp. 85-91. 11 ref.
DOCUMENT TYPE: Journal
LANGUAGE: English

AB A random sample of 941 sera from 25 non-vaccinated commercial **pig** herds distributed in Mashonaland East Province was examined for Leptospira interrogans antibodies using the microscopic agglutination test. Sera were initially screened against live antigens representing 17 serovars of **pathogenic Leptospira** at a 1:50 dilution. The overall prevalence of exposure was 33.9% with a 95% confidence interval of 30.88-37.02. Antibodies against serovar bratislava were widely distributed amongst the farms surveyed. Other antibodies detected included those against serovars cynopteri, australis, autumnalis, icterohaemorrhagiae, grippotyphosa, canicola, javanica and pomona. These results indicate that some serovar bratislava might be a contributing factor to low reproductive performance in some **swine** herds in Zimbabwe, and that the vaccine in current use, which contains other serovars, might not protect against it.

Novel expression cassette (EC) for expressing a vaccine antigen in a plant cell, comprises a DNA sequence encoding at least 1 vaccine antigen, providing protection against mucosal diseases, operably linked to transcriptional and translation control regions functional in the plant cell. Also claimed are: (1) transformed plant cell comprising the EC; (2) transgenic plant comprising the EC stably integrated into its genome; (3) transgenic plant seed comprising the EC stably integrated into its genome; and (4) animal feed composition comprising the transgenic plant or seed.

USE - The transgenic plant or seed, as part of a claimed immunogenic composition, can be used to protect animals, e.g. **pigs**, cows, sheep, goats, dogs or cats, against mucosal diseases, e.g. Bovine Respiratory Disease Complex (BRDC), bovine and **porcine** rotavirus and coronavirus, bacterial pathogens (e.g. Pasteurella and Haemophilus spp.), dairy cattle mastitis and abortion-inducing **pathogens** (e.g. **Leptospira** spp. and Campylobacter foetus). The vaccine antigen can also be extracted and purified for other uses, e.g. diagnostic assays.

ADVANTAGE - The immunogenic compositions can effectively immunise animals via the oral root, and provide for infection prevention, symptom amelioration, mortality decrease and secretory IgA response and/or neutralising antibody induction.

AB There are two types of infection caused by **pathogenic** microorganisms, intracellular infection and intercellular infection. Infection of **pathogenic leptospira** is an intercellular infection. The immunological reaction of host to intercellular infection is unique. The potential immunogen of an expressed protein should meet three criteria: it can be degraded (by antigen-present cells in the host); it should have antigenic epitope which can be recognized by specific antibodies and have at least one epitope that can be recognized by an MHC II protein and T cell receptor. In this study we report the cloning of an L. interrogans protein in plasmid rpDJt and the immunogencity of the expressed protein derivative. A genomic library of L. interrogans serovar lai strain 017 was constructed with the plasmid vector pUC18. Recombinant plasmids, designated pDJH2 and pDJ8 were screened from the bank. EcoRI-inserted fragment of 1. 9 kb recombinant DNA of pDJH2 was ligated into T7 RNA polymerase/promoter vectors (pT7-7). Then they were transformed into E. coli JM109 (De3), one of subclones, designated rpDJt was achieved. SDS-PAGE showed that the molecular weights of expression proteins were 68 kd and 23 kd respectively, designated p68 and p23. Purifying and isolating p68 and p23, we separated them from SDS-Polyacrylamide gels by using Side-Strip method. After fragmenting and electroeluting, p68 and p23 were injected into guinea **pigs** and rabbits. An extremely strong immune response to p68 was obtained since an anti-p68 antibody response could be detected to a dilution 1:524,288 (guinea **pigs**) and 1:262,144 (rabbits) by ELISA while anti-P23 antibody being 1:1024 (the same to guinea **pigs** and rabbits). The results of improved MTT and conA 3HTdR transformation methods showed the activities and proliferation of Th-cells were increased in guinea **pigs** after p68 immunization (IL-6, 83.25 IU/ml, IL-2, 28.75 IU/ml; RPI, 2.04, SI, 65.62%) Thlymphocyte existed in two subclasses, the Th1- and Th2-cells. A major role of Th2-cells is to "help" B-cells differentiate, replicate, and secrete antibody. The properties of these interactions explain why p68 makes good antigen and p23 does not. The antigens responsible for eliciting the production of protective antibodies are not known; however, several outer membrane proteins on L. interrogans are candidates for vaccine. Our results suggest that expresion protein p68 from recombinants (rpDJt) may be a candidate for gene engineered subunit vaccine for Leptospirosis.

ENTRY MONTH: 199509
AB Comparative analysis of the enzymatic profiles of 58 spirochaetal isolates clearly differentiated borrelias from leptospires, serpulinas and a treponeme. Strains of both Borrelia burgdorferi and Borrelia hermsii characteristically produced significant amounts of leucine arylamidase. This enzyme activity was not unique to borrelias but was also detected amongst **pathogenic** and non-**pathogenic leptospira** serovars. This fact, however, did not hamper a correct differentiation of borrelias from these spirochaetes, because leptospires possessed unique enzyme profiles. The API ZYM system could not differentiate the human strains of B. burgdorferi from those isolated from ticks, or from B. hermsii. Treponema phagedenis could be differentiated from all the other spirochaetes by the production of alpha-fucosidase. Our results confirm and extend previous studies indicating that human and animal intestinal spirochaetes have many common enzyme activities. All strains produced reactions of maximum intensity when tested for the presence of beta-galactosidase activity. However the avian strains lacked esterase (C4) which was present in human and **swine** intestinal spirochaetes. All strains of Serpulina hyodysenteriae, and Serpulina innocens as well as the human intestinal spirochaete strain HRM-14 showed alpha and beta glucosidase activity. Both enzyme activities were absent or

insignificant in most other intestinal spirochaetes examined: 25 different human strains, non-pathogenic **swine** strain M1 and the avian strain 4742. However, **swine** strain LL3 and avian strain 1380 showed some beta-glucosidase activity.

Polypeptide (I) having the amino acid sequence of OmpL1 (Leptospira outer membrane protein) is new. The 320 amino acid sequence of (I) from L. alstoni is reproduced together with its genomic DNA sequence. Also new are (1) nucleic acid (II), RNA or DNA, encoding (I); (2) recombinant expression vectors contg. (II); (3) host cells transformed with these vectors; and (4) antibodies (Ab) that bind OmpL1.

USE/ADVANTAGE - (I) Is useful in vaccines to protect against Leptospira, e.g. in humans, **pigs** and cattle. Opt. labelled (I), (II) and Ab can be used in standard immunoassay/hybridisation steps to detect pathogenic heptospira (this includes in vivo imaging) or associated antibodies, for diagnosis or monitoring. Ab can also be used for immunotherapy, opt. coupled to a therapeutic agent. Since the gene for (I) is present in all **pathogenic** (but not in non-**pathogenic**) **Leptospira** examined, it should be able to provide protection against, or detection of, a wide range of serovars. Vaccinating doses are 10-1000 (pref. 50-300) microg, given by injection, orally or by nasopharyngeal or dermal absorption, with usual adjuvants. Antibody doses are 0.1-2000 (pref. 0.1-500)mg/kg. by injection, opt. together with effector cells.

AB We have developed an assay for the detection of **pathogenic** **Leptospira** that is based on the polymerase chain reaction.

With the combination of agarose gel electrophoresis and blotting, **pathogenic Leptospira** can be discriminated specifically from nonpathogenic **Leptospira** and other bacterial species. This method, based on the amplification of 16S ribosomal RNA sequences, is able to detect 10 leptospiral cells/mL in cattle urine samples and 100 leptospiral cells/mL in **pig** urine samples. Using this assay leptospires were detected in urine samples from cattle that were experimentally infected with Leptospira interrogans serovar hardjo type hardjobovis.

The allergen is produced as follows. The Leptospira serotypes, Pomona, Tarassovi, Icterohaemmorrhagiae, Canicola, Sexahoebing and Grippotyphosa are cultivated separately in bottles contg. water-serum nutrient medium at pH 7.2-7.4. After incubation at 28-30 deg.C for 7-10 days, selected cultures are amalgamated in one vessel, then subjected to ultrasound (20 kHz, 100 W) for 20 min. The disintegration prod. is then autoclaved at 1 atmos. for 20 min. and centrifuged at 2500 rev/min. for 30 min. Finally, the supernatant is filtered.

USE/ADVANTAGE - The process is used to obtain allergens for carrying out intradermal allergic reactions in animals. Specific

delayed hypersensitivity to Leptospira pathogens can be determined. The quality of the allergen is enhanced.

In an example, prepn. specificity was evaluated using non-immune laboratory **pigs**, infected intraperitoneally with virulent **Leptospira** cultures and having **pathogen** antibodies in titre of 1:100 or over. Allergen injected subcutaneously produced a positive reaction in the form of an intumescent area measuring 2-2.5 x 2-2.5 cm2.

AB The outer membrane proteins of seven reference strains of **pathogenic Leptospira** (L. alstoni serovar grippotyphosa, L. borgpetersenii serovar hardjo, and L. interrogans serovars autumnalis, bratislava, canicola, icterohaemorrhagiae, and pomona) were investigated to identify common surface-exposed outer membrane proteins. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis of sodium-N-lauroylsarcosinate-insoluble outer membrane enriched fractions of the reference serovars and two field isolates of serovars hardjo and pomona revealed six common protein bands with approximate molecular masses of 77, 66, 42, 35.5, 24, and 18 kDa. At times the 35.5 kDa endoflagellar band resolved into two distinct bands, 35.5 kDa and 34 kDa. Immunoblotting of the same fractions using rabbit leptospiral antibodies showed six bands to be common (66, 59.5, 44, 42, 35.5, and 18 kDa). The 44 kDa band stained poorly with Coomassie blue but prominently by immunoblotting. Four reference strains (serovars bratislava, canicola, icterohaemorrhagiae, pomona), and two field isolates of serovar pomona and one of serovar bratislava were grown in low iron media to which the iron chelators 2,2'-dipyridyl or ethylenediaminehydroxyphenylacetic acid were added. No iron-dependent expression of outer membrane proteins was observed. The only difference observed between the outer membrane proteins when reference serovars of canicola or pomona were grown in dialysis bags in the peritoneum of **swine** or in vitro was the loss

of the 77 kDa band from in vivo grown organisms. Treatment of whole leptospires with proteinase K did not remove the 77, 66, 59.5, or 42 kDa protein; these proteins may not be surface expressed or are inaccessible to the proteinase K. The 44 kDa band could not be evaluated by this method and the 18 kDa band was proteinase K resistant.

AB The spirochetes include some important **pathogenic** bacteria, Treponema, Borrelia and **Leptospira**. The pathogeneses of these spirochetes are very diverse. In an attempt to learn more about the virulence factors among the spirochetes, their genetic organization and capacity have been studied. Structural analysis of the genome in Borrelia has shown that the genome is composed of one linear maxi-chromosome with additional linear minichromosomes as well as several supercoiled circular plasmids. Moreover, the molecular analysis of the terminal ends of one of the linear minichromosomes has revealed that this unique replicon has sequence similarities with poxviruses and particularly the viral agent of African **swine** fever. The presence of nucleic-acid-containing vesicles and its possible role in mediating DNA transfer between borreliae is an additional, very interesting feature of these organisms. Treponema does not contain any linear DNA, chromosomal or extrachromosomal, however molecular characterization of a 2.6-kb plasmid of Treponema denticola has been performed with the aim of establishing cloning vehicles to study the virulence properties of the genus Treponema.

AB A set of 24 monoclonal antibodies (MABs) was produced against an outer envelope preparation from Leptospira interrogans serovar copenhageni. The MABs reacted in enzyme immunoassay with species-specific determinants of an antigen in the leptospiral outer envelope (OE) of **pathogenic** but not of saprophytic species

of **Leptospira**. The MABs did not agglutinate whole leptospires, nor could they opsonise homologous leptospires for phagocytosis by mouse macrophages or protect new-born guinea-**pigs** against lethal infection. The MABs reacted by Western blotting with a 35 x 10(3)-mol-wt band in OE separated on SDS-polyacrylamide gels, and also reacted with other bands to a lesser extent. The determinants to which the MABs were directed were localised in the leptospiral OE by immunogold labelling techniques.

AB DNA extracted from Leptospira interrogans serovar pomona was labelled with 32P by nick translation and used as a genomic probe to detect leptospiral DNA. The sensitivity of detection in a 10- mu l spot on nylon membranes was 160 pg of leptospiral DNA or 1.1x103 leptospires and assays with nylon membranes were somewhat more sensitive than assays with nitrocellulose membranes. The probe reacted with the **pathogenic Leptospira** interrogans hardjo and tarassovi serovars, but not with other genera of bacteria. To detect leptospires in body fluids, these were treated to free leptospiral DNA and then concentrated on membranes using a Bio-Dot apparatus. Neither serum nor urine interfered with the assay system. The DNA of leptospires added to **pig** urine was stable for at least 2 h at room temperature and for at least 20 h at -20 deg C.

AB Thirteen hybrid cell lines which produce mouse monoclonal antibodies to Treponema pallidum, the causative agent of syphilis, have been established. All of the monoclonal antibodies react with T. pallidum, Nichols strain, in ELISA and in immunofluorescence assays, but do not react with normal rabbit testicular tissue in the ELISA. Two of these antibodies were demonstrated to react with the nonpathogenic treponemes T. phagedenis, biotype Reiter, T. refringens (Noguchi strain), T. vincentii, and T. denticola (strains 11 and W), as well as with Borrelia recurrentis, **Leptospira** interrogans, serogroup Canicola, and the **swine pathogen** T. hyodysenteriae. The remaining 11 antibodies react with four recently isolated strains of T. pallidum, but with none of the related nonpathogens nor with Borrelia or Leptospira. Thus, our results to date indicate that these monoclonal antibodies may identify antigenic determinants that are specific either for T. pallidum alone or for those treponemes which are pathogenic for humans. The molecular specificities of six of the 13 antibodies were determined by Western blotting. We anticipate potential usefulness of these antibodies in the investigation of the antigenic structure of T. pallidum, the taxonomic study of the pathogenic and nonpathogenic treponemes, and in the diagnosis of syphilis.

AB The use of chemotherapeutic substances in pigs is discussed with reference to bacterial resistance, mode of action, drug combinations, side-effects and withdrawal times.
ABEX The development of resistance to penicillin, streptomycin, oxytetracycline, chloramphenicol, neomycin, sulfonamide and nitrofuran is considered with reference to streptococci, staphylococci, Pasteurella, Clostr. perfringens, Corynebact.,

Haemophilus, Bordetella, Erysipelothrix insidiosa, E.coli, Salm.typhimurium, S. chollerae suis and s. c. suis var. kunzendorf. Data are reproduced on the sensitivity of Mycoplasma, **Leptospira**, Borrelia, rickettsias, Bac.anthracis, Listeria, Klebs. and other **pathogens** to benzylpenicillin, sulfonamide + trimethoprim, turimycin, tylosin and most of the drugs mentioned above. Bacteriostatic action is considered in relation to the capacity of the **pig**'s defense mechanisms to destroy pathogens. The use of drug combinations, sulfonamide + trimethoprim and penicilin + streptomycin, is examined. The attainment of MICs at sites of action is discussed with reference to S. typhimurium and E.coli. Factors determining the route of administration of a drug are explained. Side-effects of broad-spectrum antibiotics may include the multiplication of yeasts and Ps.sp. Excessive doses of furazolidone or sulfonamides in **piglets** can cause CNS disorders. Procaine benzylpenicillin in aqueous suspension at 10,000 IU/kg body weight produces nausea and vomiting. S.c. injection of drugs at the base of the ear is preferable to i.m. administration in the femoral muscles of the hind leg, which can be damaging. Waiting times between drug administration and slaughter are discussed.

AB Leptospira species are difficult to isolate from sperm specimens because rapid growth of the contaminant flora will kill the **pathogen**. The resistance of 5 **Leptospira** strains to 5 different antibiotics was examined with a view to an inhibition of such contaminant growth. Neomycin (10, 20, 30 mg/l), vancomycin (5, 8, 10 mg/l), nalidixic acid (50, 75, 100 mg/l), streptomycin (5, 8, 10 mg/l) and chloramphenicol (5, 10, 20 mg/l) were added separately to Korthof's culture medium containing rabbit serum. The comparative growth rates of the leptospires were evaluated. Against the control medium, all 5 antibiotics were found to have an adverse influence on the multiplication phase. In conformity with literature

data, vancomycin (10 mg/l) and nalidixic acid (50 mg/l) were found to have the lowest effect. In the cases of streptomycin and chloramphenicol, there was a high reduction of the leptospiral count and even a complete lack of multiplication. A combination of vancomycin (10 mg2l) and nalidixic acid (50 mg/l) was used for the recovery of leptospires from **porcine** sperm. To inhibit a growth of Ps. aeruginosa, 5000 U/l polymyxin B were added. The strongly inhibitory action of polymyxin B on leptospiral growth could be eliminated by subculturing in a medium free from inhibitory substances after 2 days.

AB Leptospirin for the diagnosis of leptospirosis by an intracutaneous test contains antigenic material from 5 **pathogenic** **Leptospira** serotypes (10). During experiments with rabbits and **pigs**, leptospirin was injected into 6 **pigs** which had been infected artificially with apathogenic Leptospira biflexa serotypes patoc and sao paulo. Three out of the 6 **pigs** showed a positive leptospirin reaction (11). This interfering reaction in animals having been infected with apathogenic L. biflexa was the reason to investigate the occurrence of biflexa antibodies in **pigs** from different areas in Germany by the microscopic agglutination. None of the 854 **pigs** showed biflexa antibodies producing a 50% agglutination at a serum dilution of 1:100. If at all, **pigs** may become infected naturally by L. biflexa; this apparently seems to be a rare incident. An impairment of the diagnostic value of leptospirin by L. biflexa antibodies can be excluded.

AB A comparative study was made of the behaviour of 12 different strains of **pathogenic Leptospira** in primary trypsinized cultures of embryo kidney cells of cattle, **pigs** and guinea-**pigs**. The serological groups studied were pomona, grippotyphosa, hebdomadis and tarassovi originating from **pigs**, cattle or rodents, and also the saprophytic group semaranga. Leptospires of the grippotyphosa serogroup showed the greatest cytopathic effect (CPE) against bovine cells, and changes in the cell nuclei occurred three times more quickly than in control

cell cultures. The pomona and tarassovi serogroups were most active against **porcine** cells, and pomona and grippotyphosa against guinea-**pig** cells. L. osetica of the tarassovi serogroup also caused nuclear changes in guinea-**pig** cells 31/2 times more quickly than control cell changes. Saprophytic leptospires showed no CPE.

AB Sewage effluent and sludge from the purification plant of 8 large piggeries was examined for the presence of pathogenic leptospires. By using the methods of Appelman and Van Thiel it was found that 43.1% of samples of effluent were contaminated with L. pomona and O. tarassovi. Altogether 33 strains of pomona and three mixed cultures of pomona and tarassovi were obtained. The isolated strains were shown to be pathogenic by experimental infection of guinea-pigs, rabbits and pregnant and non-pregnant sows. The average period of survival of pathogenic leptospires in sewage effluent was 24 to 48 hours, with a maximum of 96 hours. Leptospires were killed within 24 hours in decanted sludge, owing to its strong acidity.

ENTRY MONTH: 197602

AB Experimental leptospirosis with **Leptospira** icterohaemorrhagiae Shibaura strain was studied in guinea **pigs**. When the **pathogen** was inoculated intracutaneously to the back of the animals, localized haemorrhage was observed at the inoculated site before the appearance of general haemorrhage. The severity of the local lesion increased progressively until the 7th day of inoculation. The minimum infective dose (MID) or the 50% infective dose (ID50) of the leptospiral suspension was determined by the appearance of the macroscopic local haemorrhage 7 days after inoculation. The MID thus determined was almost comparable with the value determined by the development of general symptoms and signs by conventional ip inoculation. The number of the pathogen per ID50 varied between 6 and 35 in five experiments. The local haemorrhage was effectively protected by active or passive immunization. Microscopically, haemorrhage at the inoculated site was found mainly in the dermis, directly beneath the epidermis in particular, and accompanied with leakage of the pathogen. The pathogen was also detected abunduntly in the thickened epidermal layer covering the inoculated area as well as in the epithelial matrix of hair-follicle, probably due to the proliferation of the pathogen at the site.

AB One hundred and thirty kidneys collected from apparently normal slaughtered **pigs** over a 3 year period resulted in 70 Leptospira isolations. The isolates were identified as tarassovi, pomona and canicola serotypes. Randomly selected sera from 192 animals demonstrated a high percentage of reactors to tarassovi (63.5%), pomona (64.0%) and to a lesser degree to 10 other **Leptospira** serotypes. This study confirms that **swine** are important hosts of **pathogenic leptospiras** and that this animal species should be given preferential attention in epidemiological studies and control activities.

AB Leptospira were isolated from the kidney of a toad, Bufo marinus, in the Philippines, showing the cultural characteristics peculiar to **pathogenic leptospirae**. It was proven to infect guinea **pigs** and hamsters. This **Leptospira** presents antigenic characteristics different from those of all serotypes of **pathogenic leptospirae** so far. For the serogroup and for the serotype to which this leptospira is attributed, respectively the names 'bufonis' and 'Carlos' are suggested.

AB We have developed an assay for the detection of pathogenic Leptospira that is based on the polymerase chain reaction. With the combination of agarose gel electrophoresis and blotting, pathogenic Leptospira can be discriminated specifically from nonpathogenic Leptospira and other bacterial species. This method, based on the amplification of 16S ribosomal RNA sequences, is able to detect 10 leptospiral cells/mL in cattle urine samples and 100 leptospiral cells/mL in pig urine samples. Using this assay leptospires were detected in urine samples from cattle that were experimentally infected with Leptospira interrogans serovar hardjo type hardjobovis.

Journal code: GO7. ISSN: 0019-9567.

AB Interactions of Leptospira interrogans with cultured endothelial and kidney epithelial cells were assayed by examining (i) cytoadherence of intrinsically radiolabeled leptospires to eucaryotic cell monolayers and (ii) penetration of leptospires through cell monolayers grown on polycarbonate filters in chemotaxis chambers. L. interrogans serovars attached to cultured cells in a dose- and time-dependent manner. Adherence was diminished following pretreatment of organisms with proteases, rabbit immune serum, or heat. When observed by scanning electron microscopy, most leptospires attached by both ends, rather than just one tip like Treponema pallidum. In penetration assays, 9.7% of added L. interrogans migrated through the monolayer-filter barrier, while only 0.3% of L. biflexa penetrated in the same time interval. Transmission electron microscopy revealed that organisms entered the host cell cytoplasm. These in vitro results indicate that leptospires have an invasive capacity that may be related to pathogenicity in vivo and suggest that further investigation of interactions with host cells may enhance knowledge of leptospiral virulence.

SO FOLIA PARASITOLOGICA, (1983) 30 (3) 269-75.
Journal code: F2T. ISSN: 0015-5683.

AB The virulent, murine Leptospira pomona strain isolated from Apodemus agrarius was used in an experimental infection of six pigs aged 4--5 months. The clinical course of the infection was inapparent, both the blood picture and the uptake of food were normal. All infected pigs produced antibodies against L. pomona at titres from 1:3 200 to

1:50 000. The reisolation of leptospires from the blood of the infected pigs was successful in one case only, and that on day two p.i. Throughout the course of our experiment, no microscopic evidence was obtained of the presence of leptospires in the blood of the infected animals. Of the six guinea pigs injected repeatedly with the urine of the infected pigs, antibodies against L. pomona were detected in two of these at titres 1:3 200 and 1:6 400. However, no direct proof was obtained of leptospires in their kidneys. Leptospires were isolated from the kidneys of two of the infected pigs, at days 10 and 21 p.i. respectively. As suggested by our results, the Central European, murine Leptospira pomona strain should be regarded as an independent biovar incapable of causing a long-term leptospiruria and, hence, apparently unable to result in an epizooty in intensive pig husbandry. According to experimental evidence, Mus musculus can be a potential reservoir of the murine L. pomona biovar in Central Europe.

AB Sewage effluent and sludge from the purification plant of 8 large piggeries was examined for the presence of pathogenic leptospires. By using the methods of Appelman and Van Thiel it was found that 43.1% of samples of effluent were contaminated with L. pomona and O. tarassovi. Altogether 33 strains of pomona and three mixed cultures of pomona and tarassovi were obtained. The isolated strains were shown to be pathogenic by experimental infection of guinea-pigs, rabbits and pregnant and non-pregnant sows. The average period of survival of pathogenic leptospires in sewage effluent was 24 to 48 hours, with a maximum of 96 hours. Leptospires were killed within 24 hours in decanted sludge, owing to its strong acidity.

AB Novel isolates of the spirochaete Leptospira and antigens derived from them that can be used in the diagnosis and prophylaxis of disease are described. More particularly, the present invention is directed to a new serovar of Leptospira designated as serovar **hurstbridge** or serogroup **Hurstbridge** or L. fainei. The bacteria were isolated from pigs at slaughterhouses in Australia. The new isolate is a member of the **pathogenic** grouping of **Leptospira** but is distinct from known serovars. It is most similar to the lyme serovar of L. inadai.

AB **Pathogenic leptospires** can be causative agents of reproductive problems in pigs. Cultures of uteri and kidneys from two pig herds in New South Wales and Victoria (Australia) yielded five strains identified as Leptospira on morphol. and cultural grounds. Phenotypic characteristics (growth at 13 and 30.degree.C, growth in the presence of 8-azaguanine) were intermediate between those of **pathogenic** and saprophytic **leptospires**. No cross-agglutination was obsd. with ref. antisera representing the 24 pathogenic serogroups and the main saprophytic ones. Antiserum against one of the strains did not agglutinate ref. strains representative of any serogroup. This provided evidence of a new serovar, designated **hurstbridge** . Genomic characterization of the five strains was achieved using five mol. approaches. Mapped restriction site polymorphisms in the rrs (16S rRNA) gene were not related to those of any ref. strains. Arbitrarily primed PCR fingerprints suggested clonality of the five strains. The strains all showed an identical and unique PFGE

profile. PCR, using primers specific for the rrs gene of **pathogenic leptospires**, amplified corresponding sequences from the strains. DNA-DNA hybridization (and reciprocal expts.) using the S1 nuclease/TCA method was performed between one of the strains and the ref. strains of Leptospira species. The homol. ranged from 0 to 36% (the latter being with Leptospira inadai) thus satisfying the criterion of a new species, Leptospira fainei (type strain BUT 6T). Phylogenetic anal. of 16S rRNA sequences showed that L. fainei and L. inadai formed a clade sep. from the previously recognized "saprophyte" and "pathogen" clades.

AB A set of 723 diagnostic sera from human patients, submitted for the microscopic agglutination test (MAT) for antibodies to a group of 6 leptospiral serovars, was also tested by MAT for antibodies to the recently-discovered Leptospira fainei serovar **hurstbridge**. MAT titres of > or = 128 to serovar **hurstbridge** were detected in 13.4% of these sera, and titres of > or = 512 in 7.2%. In contrast, none of 62 sera obtained from a control population of laboratory staff gave titres of > or = 128. The difference between the number of titres of > or = 128 given by the two groups of sera was highly significant ($P < 0.01$). The titres observed may have been due to cross-reactions with other leptospiral serovars, but this could not be demonstrated. An alternative explanation is that serovar **hurstbridge** is present in the human population.

AB A set of 10 440 sera was collected from pigs slaughtered at Victorian abattoirs. These sera were subjected to the microscopic agglutination test for antibodies to Leptospira interrogans serovar pomona. Identification of the herd of origin was possible for 6511 pigs, and these were derived from 167 herds in Victoria (84% of sera), from 32 herds in New South Wales (8% of sera) and 29 herds in South Australia (8% of sera). The overall prevalence of titres of 512 and above was 3.7%. This was higher (5.3%) among pigs for which the property of origin was unknown than among pigs with identified properties of origin. Among the latter the prevalence was 2.7% (Victoria 0.6%, New South Wales 1.3%, South Australia 25.2%.) Most of the pigs with unknown properties of origin were derived from market groups and were probably typically from smaller herds. Within Victoria a comparison of results with the known pig populations of the 12 statistical divisions indicated that infection was spread throughout the State. Of the 228 identified herds of origin sampled, 32 (14%) had at least one pig with a high titre. However, this may underestimate the proportion of infected herds, as in many cases only a few serum samples were obtained. Of 73 herds from which 25 or more serum samples were obtained, serological evidence of infection was obtained in 18 herds (25%).

AB The aim of this study was to determine whether evidence could be obtained of foetal infection with **Leptospira** interogans serovar hardjo in aborted foetuses collected from diary farms.

Material from 197 abortions occurring over a wide area of Victoria was collected over 3 years. None of 195 foetal kidney cultures or 7 cultures from membranes was positive for **leptospiral** organisms. Immunogold silver staining for **leptospires** was performed on sections of kidneys, lungs or heart from 156 foetuses, with negative results. Evidence of transient **leptospiral** infection in 11 of 123 foetuses was obtained by foetal heart blood serology. Two isolates of L. interrogans serovar hardjo were obtained from the urine of milking cows. These strains were examined by restriction endonuclease analysis and both were shown to be of the genotype Hardjobovis, as have been all Australian isolates studied so far. It appears that foetal infection was serovar hardjo is not associated with any substantial proportion of bovine abortions in Victoria, in contrast to the situation in Northern Ireland. The apparent absence from Victoria of the **pathogenic** genotype hardjoprajitno is a possible explanation.

AB DNA extracted from **Leptospira** interrogans serovar pomona was labelled with phosphorus-32 by nick translation and used as a genomic probe to detect **leptospiral** DNA. The sensitivity of detection in a 10-microliter spot on nylon membranes was 160 pg of **leptospiral** DNA or 1.1 X 10(3) **leptospires** and assays with nylon membranes were somewhat more sensitive than assays with nitrocellulose membranes. The probe reacted with the **pathogenic** hardjo and tarassovi **leptospiral** serovars, but not with other genera of bacteria. To detect **leptospires** in body fluids, these were treated to free **leptospiral** DNA and then concentrated on membranes using a Bio-Dot apparatus. Neither serum nor urine interfered with the assay system. The DNA of **leptospires** added to pig urine was stable for at least 2 h at room temperature and for at least 20 h at -20 degrees C.
